MEMORANDUM May 31, 2005

To:

John D'Antonio, State Engineer

Stanley Pollack, Counsel, Navajo Nation Department of Justice

John Stomp, Water Resources Division Manager, City of Albuquerque

Copy:

Estevan Lopez, Interstate Stream Engineer

Jim Dunlap, Chairman, Interstate Stream Commission DL Sanders, Chief Counsel, Office of the State Engineer

John Utton, Counsel, Office of the State Engineer

Nate Gentry, Staff, Senate Energy and Natural Resources Committee

Erik Webb, Staff, Office of Senator Pete Domenici Mike Connor, Staff, Office of Senator Jeff Bingamin

From:

John Whipple, Staff, Interstate Stream Commission

Subject:

Institutional Processes and Computational Procedures for Implementing

Section 11 of the Act of June 13, 1962, Public Law 87-483

BACKGROUND

Representatives of the Office of the State Engineer, the Navajo Nation, the City of Albuquerque and New Mexico's Congressional delegation met on March 29, 2005, to discuss the City of Albuquerque's concerns regarding possible impacts of the San Juan River Basin in New Mexico Navajo Nation Water Rights Settlement Agreement on the availability of water for the San Juan-Chama Project. As part of the discussion, the City proposed that a working group be established to develop institutional processes and computational procedures for implementing the water allocation formula of section 11 of the Act of June 13, 1962, Public Law 87-483, during years of shortage (see John Stomp's March 28, 2005, Inter-Office Correspondence to Congressional staff on Hydrologic Impacts and Recommendations for the Navajo Nation Water Rights Settlement Agreement, at page 4). Existing processes and procedures, and additional direction and guidance to the Secretary of the Interior that is proposed by the Settlement Agreement, are as follows.

WATER ALLOCATION FORMULA OF SECTION 11 OF PUBLIC LAW 87-483

Section 11 of Public Law 87-483 provides, in pertinent part:

(a) No person shall have or be entitled to have the use for any purpose, including uses under the Navajo Indian irrigation project and the San Juan-Chama project authorized by sections 2 and 8 of this Act, of water stored in Navajo Reservoir or of any other waters of the San Juan River and its tributaries originating above Navajo Reservoir to the use of which the United States is entitled under these projects except under contract satisfactory to the Secretary [of the Interior] and conforming to the provisions of this Act. Such contracts, which, in the case of water for Indian

uses, shall be executed with the Navajo Tribe, shall make provision, in any year in which the Secretary anticipates a shortage, taking into account both prospective runoff originating above Navajo Reservoir and the available water in storage in Navajo Reservoir, for a sharing of the available water in the following manner: The prospective runoff shall be apportioned between the contractors diverting above and those diverting at or below Navajo Reservoir in the proportion that the total normal diversion requirement of each group bears to the total of all normal diversion requirements. In the case of contractors diverting above Navajo Reservoir, each such contract shall provide for a sharing of the runoff apportioned to said group in the same proportion as the normal diversion requirement under said contract bears to the total normal diversion requirements of all such contracts that have been made hereunder: Provided. That for any year in which the foregoing sharing procedure either would apportion to any contractor diverting above Navajo Reservoir an amount in excess of the runoff anticipated to be physically available at the point of his diversion, or would result in no water being available to one or more such contractors, the runoff apportioned to said group shall be reapportioned, as near as may be, among the contractors diverting above Navajo Reservoir in the proportion that the normal diversion requirements of each bears to the total normal diversion requirements of the group. In the case of contractors diverting from or below Navajo Reservoir, each such contract shall provide for a sharing of the remaining runoff together with the available storage in the same proportion as then normal diversion requirement under said contract bears to the total normal diversion requirements under all such contracts that have been made hereunder.

...

The procedures to be followed and the steps to be taken to implement section 11 of public Law 87-483 were set forth in mathematical terms of formulas provided by the US Bureau of Reclamation in Navajo Indian Irrigation and San Juan-Chama Participating Projects, New Mexico, 85th Congress, 2nd Session, Senate Report No. 2198, August 5, 1958, at pages 67-69, as follows:

The evaporation factor E is here handled as a reduction to inflow. By this process water users above, below, and from Navajo Reservoir stand a share of the Navajo Reservoir evaporation loss. The principle could also apply if evaporation was considered as an addition to, or part of, total demand. In this latter event, it would be necessary to assign a share of the evaporation loss to the group of contractors above Navajo and to the group below such that $D_a + D_b$ would continue to equal D_a , even though D_a contained the evaporation factor D_a .

The results of the two methods could be the same by appropriate assignment of the evaporation factor E. For simplicity, however, the first-described method has been adopted herein. Evaporation cannot here be considered a reduction in available water stored in Navajo Reservoir as to do this would require only those users from or below Navajo to stand the evaporation loss.

In those years in which a shortage is anticipated, or has been determined to exist under the terms of section [11], it will be necessary to make at least monthly estimates of inflow and storage content, with corresponding adjustments if needed in apportioned supply.

Definitions of the symbols used in the formulas are as follows:

- R =Available water stored in Navajo Reservoir.
- E =Estimated evaporation for year concerned.
- I = Anticipated or forecasted inflow (minus uses not subject to sharing) into Navajo Reservoir for year concerned. ($I = I_a + I_b$).
- I_a = Available runoff (inflow) apportioned to the group of contractors above Navajo Reservoir.
- I_b = Available runoff (inflow) apportioned to the group of contractors below Navajo Reservoir.
- I_p = Available runoff physically available at point of contractor's diversion.

- D = Total normal diversion requirements of all contractors. $(D = D_a + D_b)$.
- D_a = Total normal diversion requirements of the group of contractors above Navajo Reservoir.
- $D_{a 1, 2, 3}$, etc. = Normal diversion requirements of respective contractors diverting above Navajo Reservoir.
 - D_b = Total normal diversion requirements of [the] group of contractors diverting from or below Navaio Reservoir.
- $D_{b 1, 2, 3}$, etc. = Normal diversion requirement[s] of respective contractors diverting from or below Navajo Reservoir.

Step 1-Determination of water shortage

"Such contracts shall make provision, in any year in which the Secretary anticipates a shortage taking into account both the prospective runoff originating above Navajo Reservoir and the available water in storage in Navajo Reservoir, for sharing available water * * *."

A water shortage is determined to exist when the available water stored in Navajo Reservoir (R) and the anticipated or forecasted inflow into the reservoir (I) is less than the total normal diversion demand of all contractors, or

$$R + (I - E) < D$$

Step 2-Apportionment of available water supply between contractors above and those at or below Navajo Reservoir

In the event it is determined by step 1 that a water shortage exists, the prospective runoff, the right to which the United States is entitled as defined in the proposed amendment to section [11], would be "apportioned between the contractors diverting above and those diverting at or below Navajo Reservoir in the proportion that the total normal diversion requirement of each group bears to the total of all normal diversion requirements," or

The share of available inflow for the group of contractors above Navajo Reservoir, (I_a) , is

$$\frac{D_a}{D} \times (I - E)$$

The share of available inflow for the group of contractors below Navajo Reservoir, (I_b) , is

$$\frac{D_b}{D} \times (I - E)$$

Step 3-Sharing of available runoff apportioned to contractors above Navajo Reservoir

"In the case of contractors diverting above Navajo Reservoir, each such contract shall provide for a sharing of the runoff apportioned to the said group in the same proportion as the normal diversion requirement under said contract bears to the total normal diversion requirements of all such contracts," or

$$\frac{D_{\underline{a}\underline{1}}}{D_{a}} \times I_{a}$$
,

$$\frac{\underline{D}_{\underline{a}\underline{2}}}{D_a} \times I_a$$
,

and so forth, for each of those contractors.

Step 4-Reapportionment when water apportioned is in excess of runoff available to contractor above Navajo Reservoir

"Provided, That for any year in which the foregoing sharing procedure either would apportion to any contractor diverting above Navajo Reservoir an amount in excess of the runoff anticipated to be physically available at the point of his diversion, or would result in no water being available to one or more such contractors, the runoff apportioned to said group shall be reapportioned as near as may be among the contractors diverting above Navajo Reservoir in the proportion that the normal diversion requirement of each bears to the total normal diversion requirements of the group.

Actually, the manner of handling this provision will depend upon physical factors of amount of diversion and respective locations of points of diversion of contractors to each other. In general, the provision would be accomplished in the following manner when the procedure of step 3 results in apportioning more water to a contractor (D_{a1}) than is physically available at his point of diversion:

$$\begin{aligned} D_{a1} &= I_p \\ & \underline{D_{a2}}_{D_a - D_{a1}} \times (I_a - I_p) \\ & \underline{D_{a3}}_{D_a - D_{a1}} \times (I_a - I_p), \end{aligned}$$

And so forth.

Step 5-Sharing of remaining available runoff and available stored waters among contractors at or below Navajo Reservoir

"In the case of contractors diverting from or below Navajo Reservoir each such contract shall provide for a sharing of the remaining runoff together with the available storage in the same proportion as the normal diversion requirement under said contract bears to the total normal diversion requirements under all such contracts," or

$$\frac{D_{b1}}{D_b} \times (I_b + R)$$

$$\frac{D_{b2}}{D_b} \times (I_b + R)$$

$$\frac{D_{b3}}{D_b} \times (I_b + R),$$

and so forth, for each of those contractors.

Other than San Juan-Chama Project contractors, contractors for water from the Navajo Reservoir water supply are the Navajo Nation for irrigation uses on the Navajo Indian Irrigation Project, the Jicarilla Apache Nation for uses pursuant to the Jicarilla Apache Tribe Water Rights Settlement Act (Public Law 102-441), the Hammond Conservancy District for uses on the Hammond Irrigation Project, and Williams Gas. The Hammond Conservancy District contract for 23,000 acre-feet of diversion is perpetual, but the Williams Gas contract for 50 acre-feet of diversion expires in 2028. The Jicarilla Apache Nation's settlement contract for up to 33,500 acre-feet of diversion and 25,500 acre-feet

of depletion per year is perpetual, and the Nation subcontracts water for uses diverting below Navajo Reservoir, including for 16,200 acre-feet of diversion and depletion by the Public Service Company of New Mexico at the San Juan Generating Station beginning 2006 and ending 2027 and for several small uses under short-term subcontracts. The Navajo Nation's contract for diversion of up to 508,000 acre-feet per year for use on the Navajo Indian Irrigation Project would be superceded by the settlement contract proposed as part of the San Juan River Basin in New Mexico Navajo Nation Water Rights Pursuant to the Settlement Agreement and the proposed Settlement Agreement. authorization of the Navajo-Gallup Water Supply Project, the Navajo Nation also would be entitled to receive under the proposed settlement contract up to 22,650 acre-feet of diversion and 20,780 acre-feet of depletion for its uses in New Mexico under the project. If Congress authorizes the Navajo-Gallup Project, the Jicarilla Apache Nation would use 1.200 acre-feet of its contract water supply through the project and would subcontract 7,500 acre-feet of its contract supply for long-term use by the City of Gallup for its share of the project.

DIRECTION TO SECRETARY IN NAVAJO SETTLEMENT AGREEMENT

It is the responsibility of the Secretary of the Interior pursuant to section 11 of Public Law 87-483 to determine whether an anticipated shortage exists, and to determine and apportion the available runoff and storage in accordance with the principles of section 11. Nonetheless, with the possibility of shortages during the recent drought and the possibility of increased demands on the Navajo Reservoir water supply if the Navajo-Gallup Water Supply Project is authorized and constructed, some Navajo Reservoir water supply contractors in the San Juan River Basin and some San Juan-Chama Project contractors in the Rio Grande Basin raised questions as to how the Secretary of the Interior might determine the normal diversion requirements of contractors.

Since passage of Public Law 87-483 in 1962, the United States pursuant to New Mexico State Engineer Permit No. 3215 appropriated 500 cfs of inflow to the San Juan River arising below Navajo Dam to supplement the water supply available at Navajo Reservoir for meeting the diversion demands under Navajo Reservoir water supply contracts. Also, facilities of the Navajo Indian Irrigation Project have been completed to provide water service to about 75 percent of the acreage authorized for the project. The Navajo Nation in three cooperative agreements, which are the Recommendations for San Juan River Administration and Operations for 2003, for 2004 and for 2005, accepted a concept that its diversion requirement would reflect the normal diversion requirement for the amount of acreage and for the crops it will irrigate during the year, as opposed to an authorized diversion amount that may not reflect the current project condition and demand. Certainly, the Secretary in making determinations of normal diversion requirements may consider the use of water available to the United States under Permit No. 3215 to meet diversion requirements of contractors diverting below Navajo Reservoir and the current year demands for water originating above Navajo Reservoir to meet the diversion requirements of contractors for beneficial uses during the year.

In addition, the Settlement Agreement and Navajo-Gallup Water Supply Project authorization would conditionally provide an opportunity for the Navajo Nation to contract with the Secretary of the Interior for delivery of 6,410 acre-feet of water from the Navajo Reservoir water supply for its uses in Arizona under the project. Article IX of the Upper Colorado River Basin Compact provides for the storage and diversion of water in an upper signatory state for consumptive use in a lower signatory state, subject to the rights of water users in the upper signatory state to receive and use water within the apportionment to such state by the compact.

As a result of public comments on the proposed Settlement Agreement, including comments submitted by the City of Albuquerque regarding occurrences and sharing of shortages pursuant to section 11 of Public Law 87-483, section 403 of the settlement act that is Appendix 3 to the Settlement Agreement would provide the following additional direction and guidance to the Secretary as to the determination of normal diversion requirements and allocations of water in a year of shortage pursuant to section 11 of Public Law 87-483:

SEC. 403. SHARING OF AVAILABLE WATER.

- (a) INFLOW BELOW NAVAJO DAM. -- Whenever water is available for diversion pursuant to New Mexico State Engineer File No. 3215, the water available shall be distributed, to the extent practical, in proportionate amounts to the diversion demands of all contractors and subcontractors of the Navajo Reservoir water supply diverting below Navajo Dam.
- (b) RUNOFF ABOVE NAVAJO DAM. -- For the purpose of implementing the shortage sharing provisions of subsection 11(a) or the Act of June 13, 1962 (76 Stat. 96; Public Law 87-483), the Secretary of the Interior shall determine amounts of shortage and apportionments of water using the normal diversion requirements on the flow of the San Juan River originating above Navajo Dam that are based on:
 - (1) the amounts of diversion or water delivery for the current year anticipated to be necessary to irrigate lands in accordance with cropping plans prepared by contractors;
 - (2) the annual diversion or water delivery demands for the current year anticipated for non-irrigation uses pursuant to water delivery contracts, including the demand for delivery for uses in Arizona under the Navajo-Gallup Water Supply Project as authorized by section 104 of Title I of this Act, but excluding any current demand for surface water for placement into aquifer storage for future recovery and use; and
 - (3) an annual normal diversion demand of 135,000 acre-feet for the San Juan-Chama Project (initial stage) authorized by section 8 of the Act of June 13, 1962.

The Secretary shall not include in the normal diversion requirements the amounts of water that reliably can be anticipated to be diverted or delivered under contract from inflows to the San Juan River arising below Navajo Dam pursuant to New Mexico State Engineer File No. 3215, or the amounts of water anticipated to be supplied through re-use. In the event that the State of New Mexico determines that water uses under Navajo Reservoir water supply contracts or diversions by the San Juan-Chama Project must be reduced in any year for New Mexico to comply with the provisions of the Upper Colorado River Basin Compact (63 Stat. 31), including, but not limited to, Article III and Article IV of the Compact, the Secretary shall reduce the normal diversion requirements if necessary to reflect water use of diversion limitations imposed by the State of New Mexico.

(c) ALLOCATION OF SHORTAGES. -- In the event of shortage, the Secretary of the Interior shall first make an allocation of shortage to the demand on the Navajo Reservoir water supply for delivery for uses in Arizona under the Navajo-Gallup Water Supply Project, up to the full amount

of demand and excluding the amounts of water anticipated to be diverted for such uses from inflows to the San Juan River arising below Navajo Dam pursuant to New Mexico State Engineer File No. 3215. Second, the Secretary shall make an allocation of shortage to the demand on the Navajo Reservoir water supply for delivery for uses allocated pursuant to subparagraph 8.2 of the Settlement Agreement, up to the full amount of demand and excluding any amounts of water anticipated to be diverted for such uses under State Engineer File No. 3215. The remaining amount of shortage, if any, shall be allocated to the normal diversion requirements for uses in New Mexico that are determined pursuant to subsection (b) of this section in accordance with the procedure for apportioning the water supply available above Navajo Dam described in subsection 11(a) of the Act of June 13, 1962 (76 Stat. 96). To determine the occurrence and amount of any shortage to contracts entered pursuant to section 11 of the Act of June 13, 1962, the Secretary shall not include as available storage any water stored in a top water bank in Navajo Reservoir established pursuant to section 405 of this Act. During years in which the Secretary determines and allocates a shortage in the Navajo Reservoir water supply, the Secretary shall not deliver, and contractors of the water supply shall not divert, any of the water supply for placement into aquifer storage for future recovery and use.

- (d) APPLICATION OF SHORTAGES. The Secretary shall apply the sharing and apportionment of water determined pursuant to subsection 11(a) of the Act of June 13, 1962 (76 Stat. 96), and subsections (b) and (c) of this section on an annual volume basis, and shall not otherwise apply or enforce a percentage or volumetric shortage to the amount of water available for diversion or delivery from the Navajo Reservoir water supply or for diversion by the San Juan-Chama Project on a day to day basis; provided, that this subsection shall not be construed to affect subsection 8(f) of the Act of June 13, 1962.
- (e) REVISIONS TO SHORTAGE DETERMINATIONS. -- The Secretary may revise determinations of shortages and apportionments of water under subsection 11(a) of the Act of June 13, 1962 (76 Stat. 96), and this section as water supply conditions materialize or change throughout the year.
- (f) COOPERATIVE WATER SHARING AGREEMENTS. -- Nothing in the Act of June 13, 1962 (76 Stat. 96), or in this Act shall be construed to prohibit the Secretary from reallocating water, including in a year of shortage, in accordance with cooperative water agreements between water users for a sharing of water supplies either between the San Juan-Chama Project and water contractors in the San Juan River Basin, subject to applicable laws.

The State of New Mexico and the Navajo Nation agree to the guidance provided by section 403 of the settlement act, and specifically to the normal diversion requirement for the San Juan-Chama Project of 135,000 acre-feet per year, only in the context of the Settlement Agreement. An example implementation of the water allocation formula of Section 11(a) of Public Law 87-483, as clarified by section 403 of the proposed settlement act, is provided in Attachment 1 for illustrative purposes. Until Congress enacts the settlement act or otherwise provides additional direction to the Secretary, the Secretary may use his or her discretion to determine the normal diversion requirement for contractors of the San Juan-Chama Project water supply based on the current year demands for contract deliveries below Heron Dam.

FLOWS FOR ENDANGERED FISH HABITAT

The San Juan River Basin Recovery Implementation Program, authorized by Public Law 106-392, in 1999 adopted quantified flow recommendations for the San Juan River below

Farmington that are believed to provide for the habitat needs of endangered fish species in the river, subject to modification through adaptive management. The US Bureau of Reclamation is preparing an Environmental Impact Statement on operating Navajo Reservoir to meet the flow recommendations, or a reasonable alternative, while also operating the reservoir to supply water to contractors of the Navajo Reservoir water supply, including the San Juan-Chama Project contractors by exchange. In consultations under section 7 of the Endangered Species Act (ESA) regarding effects of federal water projects on endangered species in the San Juan River, the US Fish and Wildlife Service has avoided jeopardy opinions by identifying as a reasonable and prudent alternative the operation of Navajo Reservoir to provide flows that promote recovery of the endangered fish species. Such section 7 consultations have been completed for the Navajo Indian Irrigation Project and the Animas-La Plata Project, is nearing completion on Navajo Reservoir operations, and have yet to be initiated for the Hammond Irrigation Project or for the San Juan-Chama Project diversions from tributaries to the San Juan River. The Recovery Implementation Program provides both reasonable and prudent alternatives to avoid jeopardy pursuant to section 7 of the ESA and reasonable and prudent measures to avoid take pursuant to section 9 of the ESA. The possibility that operating the reservoir to meet the flow recommendations might result in shortages in water supply available to meet the diversion demands of contractors is discussed in my March 22, 2005, Memorandum to Congressional staff on San Juan River Basin in New Mexico Navajo Nation Water Rights Settlement Agreement: Issues Relating to the Entitlements, Availability and Sharing of Water for Navajo Reservoir Water Supply Contracts and the San Juan-Chama Project, at pages 30-34.

The City of Albuquerque in its Comments on Navajo-Gallup Settlement, transmitted via letter from Mayor Martin Chayez to State Engineer John D'Antonio dated January 15, 2004, suggested that the San Juan-Chama Project should not share in any regulatory shortages that might be caused by implementation of the Endangered Species Act in the San Juan River Basin. John Stomp's March 28, 2005, Inter-Office Correspondence to Congressional staff on Hydrologic Impacts and Recommendations for the Navajo Nation Water Rights Settlement Agreement appears to repeat the City's suggestion. Correspondence at page 4 and the ensuing discussion with City representatives at the meeting on March 29, 2005, indicates that the proposal to form a working group to develop procedures for implementing section 11 of Public Law 87-483 may be meant to ensure that the prospective runoff to be apportioned among the contractors includes the amount of water available for environmental flows recommended by the Recovery Implementation Program so as to reduce the risk of increased sharing of shortages to the San Juan-Chama Project. In other words, the City suggests or recommends that the prospective runoff originating above Navajo Reservoir, or the anticipated inflow into Navajo Reservoir (1), would be apportioned in accordance with section 11 of Public Law 87-483, after which the releases from Navajo Reservoir required to meet the flow recommendations, or a reasonable alternative, would be supplied out of the runoff apportioned to the contractors in the San Juan River Basin only and not out of the runoff apportioned to the San Juan-Chama Project. My March 22, 2005, Memorandum at page 34 indicates that the City's suggestion is not acceptable to water users in the San Juan River Basin.

Runoff originating above Navajo Reservoir is available to the United States pursuant to State Engineer File No. 2847 for the San Juan-Chama Project, File No. 2848 for the Hammond Irrigation Project, File No. 2849 for Navajo Reservoir storage to provide water for the Navajo Project and other uses, File No. 2873 for Navajo Reservoir evaporation, and File No. 2917 for additional municipal and industrial uses to be supplied from Navajo Reservoir. The amount of runoff originating above Navajo Reservoir that is available to the United States is the inflow to the reservoir (prior to San Juan-Chama Project and Navajo Reservoir water supply contract diversions above the reservoir) less the amount of water required to be released from the reservoir to meet downstream water rights with priority dates senior to June 17, 1955, and to meet obligations of the Upper Division States under the Colorado River and Upper Colorado River Basin compacts. By definition, the prospective runoff above Navajo Reservoir available to the United States, that is, the amount of the anticipated or forecasted reservoir inflow (1) that is available to be apportioned to contractors, including the San Juan-Chama Project, is the anticipated runoff already reduced for the more senior uses that are not subject to sharing of shortages.

The water allocation formula of section 11 of Public Law 87-483 handles the evaporation factor E as another reduction to inflow. By this process, water users above, below and from Navajo Reservoir stand a share of the Navajo Reservoir evaporation loss. Evaporation cannot here be considered a reduction in available water stored in Navajo Reservoir as to do this would require only those users from or below the reservoir to stand the evaporation loss. Like evaporation loss, the flow demands to maintain populations of endangered fish species in the San Juan River contribute to the total demand on water originating above Navajo Reservoir. The demand for water from Navajo Reservoir to meet the Recovery Implementation Program's recommendations, or a reasonable alternative, thus can be handled similarly as a reduction to inflow. In this manner, water users above, below and from Navajo Reservoir stand a share of the risks of shortage in supply caused by providing flows needed to maintain populations of endangered fish species in the San Juan River. Endangered fish flows cannot here be considered a reduction in available water stored in Navajo Reservoir as to do this would require only those users from or below the reservoir to stand the burden and consequent risks of maintaining the populations of endangered fish species in the river.

In terms of the mathematical formulas presented above, either the inflow (I) can be redefined as anticipated or forecasted inflow to Navajo Reservoir minus senior uses not subject to sharing and minus releases from the reservoir made to comply with the ESA, or the test for determining whether a shortage exists can be redefined as:

$$R + (I - E - F) < D$$

where F = the demand for water originating above Navajo Reservoir to meet the habitat needs of endangered fish species in the San Juan River, which needs may be less than the flow recommendations during periods of extreme drought. Part of the habitat needs will be met from inflows arising below Navajo Dam. Nothing herein should be construed to establish or to limit any liability on the part of the United States for shortages to contract

deliveries caused by bypassing or releasing water from Navajo Reservoir for purposes of maintaining habitat for populations of endangered fish species in the San Juan River.

BUREAU OF RECLAMATION PLANNING AND CONSULTATION PROCESSES

The Bureau of Reclamation at the beginning and middle of each month updates its hydrologic study of Navajo Reservoir operations for the next 12-24 months. The study includes current reservoir storage conditions and projects inflow and storage conditions for the remainder of the year based on snowmelt runoff and reservoir inflow forecasts at various locations in the San Juan River Basin. Forecasted unregulated inflows to Navajo Reservoir are adjusted for anticipated upstream storage operations at Vallecito Reservoir and for anticipated diversions of the San Juan-Chama Project and any other contract uses above the reservoir. Anticipated San Juan-Chama Project diversions are estimated based on runoff forecasts at the points of diversion for the project and historic relationships of diversions to runoff that take into account the bypass requirements of section 8(f) of Public Law 87-483. Further reductions of project diversions are not included unless the State of New Mexico determines that such reductions are necessary to comply with the Upper Colorado River Basin Compact. The study also does not include any possible priority calls against the project during the late summer and fall months.

The reservoir operations study shows monthly water budgets for Navajo Reservoir in which Reclamation also considers inflows to the San Juan River from perennial tributaries, primarily from the Animas River, based on seasonal runoff forecasts and projections of how the runoff will materialize over time. Based on anticipated inflows to the San Juan River and anticipated water demands over time for all uses on the San Juan River, including uses under water rights with priority dates senior to June 17, 1955, and diversions at or below the reservoir under contracts and subcontracts for water from the Navajo Reservoir supply, Reclamation determines whether the amount of anticipated inflow to Navajo Reservoir plus the amount of active storage in the reservoir is sufficient to meet the demands on the reservoir while the reservoir also is operated in accordance with minimum reservoir release requirements and operational rules designed to meet the Recovery Implementation Program's flow recommendations for endangered fish habitat in the river. The operational rules include recommendations for scheduling spring peak releases under various scenarios, including scheduling releases in anticipation of spills (Corps of Engineers flood control criteria also must be followed). The study provides monthly the same water budget test of whether a shortage exists as is described by the mathematical formula: R + (I - E - F) < D.

Reclamation uses the reservoir operations study both to prepare an annual operating plan for Navajo Reservoir and to adaptively manage and adjust reservoir operations throughout the year. As part of the process to develop and implement an annual operating plan for the reservoir, Reclamation conducts three public meetings during the year to update the public on hydrologic and reservoir conditions and projected operations during the upcoming months and to receive input and suggestions from the public on reservoir operations. The meetings are held in Farmington in or about January, April and August.

The reservoir operations study typically uses the most-probable runoff forecasts; however, it also indicates possible reservoir operations under maximum-probable and minimum-probable runoff conditions. Parallel studies during the period of substantial draw down in Navajo Reservoir storage in 2003, 2004 and 2005 made pursuant to the Recommendations for San Juan River Administration and Operation for 2003, for 2004 and for 2005, respectively, utilized the minimum-probable runoff forecasts with the understanding that water users in the San Juan River Basin would plan for the maximum-probable shortage, if any, early in the irrigation season and adjust towards the most-probable shortage, if any, as the season progressed and runoff actually materialized. The most-probable and minimum-probable snowmelt runoff forecasts largely converge by about June 1. The operations study that is based on April 1, 2005, hydrological conditions and snowmelt-period runoff forecasts for the San Juan River Basin is provided in Attachment 2 for illustrative purposes.

If a shortage is projected based on the most-probable runoff forecasts, or if a shortage is possible under the minimum-probable runoff forecasts, the Bureau of Reclamation pursues avenues of cooperation for the endangered fish to share shortages with water users so as to limit shortages to users. For example, in 2003 and 2004: (1) the Hydrology Committee of the Recovery Implementation Program recognized the occurrence of extreme drought conditions in the San Juan River Basin; (2) the Biology Committee of the Recovery Implementation Program determined that a temporary reduction in the recommended target base flow for the San Juan River could reasonably be made for the year, such reduction to provide for maintenance of existing endangered fish habitat and populations, but not recovery, during the period of extreme conditions; and (3) the US Fish and Wildlife Service, in accordance with principles in the Recovery Implementation Program Document, accepted flows less than the recommended target base flow to share with water users in any shortages that might materialize. The Fish and Wildlife Service's position and practice in the Recovery Implementation Program is that the Program's flow recommendations are not sacrosanct or inviolate.

In a year of anticipated or possible shortage, Reclamation meets with representatives of the Navajo Reservoir water supply contractors, which should include representatives of the San Juan-Chama Project contractors, to review and discuss existing storage conditions, anticipated runoff conditions, contract delivery demands, diversion demands on water originating above Navajo Reservoir, endangered fish habitat flow demands, the reservoir operations study, and any other pertinent information such as extenuating circumstances regarding Navajo Reservoir operations and administration of San Juan River flows (including Navajo Reservoir releases). In 2003, 2004 and 2005, the discussions were extended to include other major water users on the San Juan River due to uncertainties as to administration of water rights on the river. The State Engineer continues to prepare to implement active water resource management, including water rights administration, in the San Juan River Basin. Representatives of the Office of the State Engineer and the Fish and Wildlife Service also participate in the meetings. The Department of the Interior then would determine the existence of any shortage and apply the above-stated procedures to apportion the water supply available in accordance with the direction given in section 11 of Public Law 87-483 and, if approved by Congress, section 403 of the settlement act; provided, that the Secretary could alternatively apportion the available supply in accordance with an allocation agreed to by the Navajo Reservoir water supply contractors, including the San Juan-Chama Project contractors.

Example Apportionment to Contractors of Water Originating above Navajo Reservoir that is available to the United States in a year of anticipated shortage pursuant to Section 11 of Public Law 87-483 and Section 403 of the Settlement Act

	Total Diversion Demand (41)	Demand Supplied From Inflows below Navajo Dam or from re-use	Normat Diversion Requirement (1)	Group Percentage of Total NM Normal Diversion Requirement (%)	Allocation of Prospective Runoff to Group (2) (af)	Water User Percentage of Group's Total Normal Diversion Requirement (%)	Apportionment of Prospective Runoff to Water User (af)	Apportionment of Available Navajo Reservoir Storage (3)	Total Apportionment of Water Available to the US above Nevajo Dam (8f)	Total Supply of Water from above Navajo Dam and from Inflows below Navajo Dam (af)
Contract uses above Navajo Reservoir.

April 5th, 2005 Navajo Reservoir AOP

Navajo Reservoir end-of-March 2005 content was about 1,182,000 af, 92% of average. Inflow to Navajo Reservoir in March was about 108,900 af, 125% of average. Releases to the San Juan River were 26,000 af (250 cfs) about 35% of average. Diversions to NIIP were 2900 af. Reservoir releases were increased from 350 cfs to 500 cfs on March 17th, 2005.

The April 5th 2005 Final Forecast was provided by the Colorado Basin River Forecast Center in Salt Lake City. This AOP is based on certain criteria and assumptions as follows:

Minimum Allowable Release: The minimum allowable release is 250 cfs from Nov 3, 2004 through March 31st, 2005. From April 1st through October 31st, the minimum allowable release is 350 cfs based on the most current and reasonable schedule for obtaining the Record of Decision (ROD) for the Navajo Reservoir EIS. The minimum allowable release will be revised to incorporate the ROD if it is signed prior November 1, 2005. (Note: Current release is 500 cfs and releases this summer will likely be higher than the minimum allowable release as a result of hydrologic conditions in the basin wich gives Reclamaition some operational flexibility.

SJRIP Target Base Flow: Maintaining the SJRIP target base flow of 500 cfs has an effect on how much water needs to be released from Navajo Reservoir. The proposed 2005 Shortage Sharing Agreement recommends that target base flows be reduced from 500 cfs to 400 cfs for the April through October period, if the Minimum Probable forecast projects the July EOM Content to be below 1,000,000 af. The April forecast does not predict this situation, so under the Minimum Probable, Most Probable and Maximum Probable inflow scenarios, the target base flow is set at 500 cfs from April through October, 2005.

The Most Probable modified-unregulated inflow forecast volume is 1,320,000 acre-feet (168% of the 30-year average) for the April-July period. After adjusting for Vallecito Reservoir operation and diversions to San Juan-Chama Project, the Apr-July inflow is projected to be about 1,087,000 af, 160% of the 30-year average. Releases are estimated to be 777,700 af for the 2005 WY and are based on forecasted Animas River flows and requirements to satisfy the SJRIP target flows. The September EOM content is projected to be 1,543,000 af, a WS Elevation of 6074.4 feet (116% of average). This shows a 608,000 af improvement over September 2004 reservoir content. This forecast indicates that no shortages would occur to Navajo Reservoir water contract users and the maximum Spring Fish Release (21 days at 5,000 cfs) would be made as determined by the Flow Recommendations. Ramping up for this release would begin on April 27th. A daily release grapah is included in this summary.

The **Minimum Probable** modified-unregulated inflow forecast volume is 960,000 af (122% of the 30-year average) for the Apr-July period. This is a 10,000 af increase from the March forecast. After adjusting for Vallecito Reservoir operation and diversions to San Juan-Chama Project, the Apr-July inflow is projected to be about 787,000 af, 116% of the 30-year average. Estimated releases of about 403,000 af for the 2005 WY are slightly increased from the March Min Probable condition. The September EOM content is projected to be about 1,570,000 af, a WS Elevation of 6076.3 feet (118% of average). This shows a 635,000 af improvement over September 2004 reservoir content. This forecast indicates that shortages would not occur to Navajo Reservoir water contract users and the minimum Spring Fish Release (7 days at 5,000 cfs)would be made as determined by the Flow Recommendations.

The **Maximum Probable** modified-unregulated inflow forecast volume is 1,750,000 acre-feet (223% of the 30-year average) for the April-July period. After adjusting for Vallecito Reservoir operation and diversions to San Juan-Chama Project, the Apr-July inflow is projected to be 1,457,000 af, 215% of the 30-year average. Releases are estimated to be 1,188,000 af for the 2005 WY and are based on forecasted Animas River flows flow and requirements to satisfy SJRIP target flows. The September EOM content is projected to be 1,530,000 af, a WS Elevation of 6073.5 feet (115% of average) under this scenario. The Maximum Spring Fish Release (21 days at 5000 cfs) would be made. In occordance with the Flow Recommendations, an additional 17 days of 4,000 cfs would be added the beginning of the Spring Fish Release to evacuate excess inflow and keep the reservoir from spilling.

One set of three graphs compare the Minimum Probable, Most Probable, and Maximum Probable February, March and April forecasts for monthly Inflow, Release and End-Of-Month Contents for the 2005 water year. A second set of three graphs compare the Minimum Probable, Most Probable, and Maximum Probable April Final forecasts for monthly Inflow, Release and End-Of-Month Contents for the 2005 water year. A third set of three graphs show the daily release schedule for the Most Probable, Minimum Probable and Maximum Probable conditions.

Assuming a 90% water supply for the 2005 water year, a spring release of

215,959 at above the base release of 500 cfs could be made next year regardless of the perturbation.

The SJRIP recommends four possible hydrograph releases. Based on the April forecast, the maximum hydrograph release is most likely this spring.
